`joren.six@hogent.be`

August 8, 2014

The main goal of this text is to bridge the gap between a mathematical description of a digital signal process and a working implementation. The text starts with calculating sound buffers, then proceeds to illustrate audio output and explains the connection between the two. Then it proceeds with operations on sound. This text is meant to be accompanying releases of the TarsosDSP audio processing library: it should clarify the concepts used in the source code.

1. Introduction

TarsosDSP is a Java library for audio processing. Its aim is to provide an easy-to-use interface to practical music processing algorithms implemented, as simply as possible, in pure Java and without any other external dependencies. This text serves two goals: it serves as a practical introduction into Music Information Retrieval (MIR) techniques for computer science students, and as documentation for the TarsosDSP library. The text assumes familiarity with object oriented programming constructs and a good knowledge of a programming language of the C-family, like Java. The concepts used should be transferable to other programming languages, or platforms as well.

TarsosDSP features implementation of the following algorithms. For each algorithm there is an example application¹ available.

- TarsosDSP was originally conceived as a library for **pitch estimation**, therefore it contains several pitch estimators: YIN [2], MPM [8], AMDF[10]², and an estimator based on dynamic wavelets[6]. There are two YIN implementations, one remains within the comforts of the time domain, the other calculates convolution in frequency domain³.
- Three **onset detectors** are provided. One described in [1], another is used by the BeatRoot system[3]. The algorithm described by [4] is also implemented.
- The WSOLA **time stretch algorithm**[13], which allows to alter the speed of an audio stream without altering the pitch is included. On moderate time stretch factors - 80%-120% of the original speed - only limited audible artifacts are noticeable.
- A **resampling** algorithm based on [12] and the related open source resample software package⁴.
- A **pitch shifting** algorithm, which allows to change the pitch of audio without affecting speed, is formed by chaining the time-stretch algorithm with the resample algorithm.
- As examples of **audio effects**, TarsosDSP contains a delay and flanger effect. Both are implemented as minimalistic as possible.
- Several **IIR-filters** are included. A single pass and four stage low pass filter, a high pass filter, and a band pass filter.
- TarsosDSP also allows **audio synthesis** and includes generators for sine waves and noise. Also included is a Low Frequency Oscillator (LFO) to control the amplitude of the resulting audio.

¹<http://tarsos.0110.be/tag/TarsosDSP>

²Partial implementation provided by Eder Souza

³The YIN FFT implementation was kindly contributed by Matthias Mauch

⁴Resample 1.8.1 can be found on the digital audio resampling home page <https://ccrma.stanford.edu/~jos/resample/>, maintained by Julius O. Smith

1.1. Developing TarsosDSP

If you are reading this text your are probably interested in the source code of TarsosDSP, either for extending the library or to use the source code as a reference. The project is hosted on GitHub⁵. Contributions to TarsosDSP are more than welcome, if you have a an algorithm to add or find a bug, do not hesitate to send me a message⁶.

TarsosDSP supports the Apache Maven⁷ and Apache Aant⁸ build systems. The instructions below detail how you can build from source. Which build system you use is upto you. When everything runs correctly you should be able to run all example applications and have the latest version of the TarsosDSP library for inclusion in your projects. Also the Javadoc documentation for the API should be available.

The library is separated in two projects. TarsosDSP contains the main core and TarsosDSP-Examples contain example applications, most with Java Swing user interfaces.

- TarsosDSP/src contains the source files of the core DSP libraries.
- TarsosDSP/test contains unit tests for some of the DSP functionality.
- TarsosDSP/target/site/apidocs contains help documentation for DSP library
- TarsosDSP/target contains MAVEN build files.
- TarsosDSPExamples/src/main contains a couple of example applications with a Java Swing user interface.
- TarsosDSPExamples/target contains build versions example applications.
- build contains ANT build files. Either to build Java documentation or runnable JAR-files for the example applications.

To make development with eclipse easy, symlink the following and make them source files in your TarsosDSP eclipse project.

```
test -f src || ln -s TarsosDSP/src/main/java/ src
test -f examples || ln -s TarsosDSPExamples/src/main/java/examples
test -f tests || ln -s TarsosDSP/src/test/java tests
```

⁸<http://ant.apache.org/>

2. Sampled Sound Using Java

To process sound digitally some kind of conversion is needed from an analog to a digital sound signal. This conversion is done by an ADC: an analog to digital converter. An ADC has many intricate properties, making sure no information is lost during the conversion. For the principle of audio processing the most important ones are the *sampling rate* and *bit depth* [9].

The sampling rate measures samples per second, it is defined in Hertz (Hz). The *Nyquist-Shannon sampling theorem*[11] states that you need to sample at twice the maximum frequency of the information you want to convey. If lower sampling rates are used, part of the information is lost. Speech is contained in the frequency range from 30Hz to 3000Hz. Applying Nyquist-Shannon, a sampling rate of 6kHz should be enough. Some telephone systems use 8kHz, which is perfect for speech signals.

The human ear is capable of detecting sounds between about 20Hz and 20kHz, depending from person to person. Sampling musical signals at about twice the maximum hearing frequency makes sense. 44100Hz, 48000Hz are common sampling rates for musical information ($20kHz \times 2 < 44.1kHz$).⁹

The bit depth is the number of bits used to represent the value of a sample. Using signed integers of 16 bits is common practice. The following example shows how these concepts translate to the Java programming language. Bit depths of 24 bits or more, and sampling rates of 96kHz or 192kHz very rarely offer any benefits for music consumers¹⁰. There is, however, an advantage for music producers to use these formats: while mixing, mending and molding music a larger dynamic range (bit depth) and sample rate prevent quality loss.

2.1. Audio buffers in Java

In this section the theoretical concepts of sampling rate and bit depth are translated to practical programming constructs. This is done by using one of the most simple audio signals, sine wave. A sine wave is characterized by a frequency f and an amplitude a . Equation 1 shows a mathematical representation of this simple audio signal.

$$f(x) = a \times \sin(2\pi f) \tag{1}$$

The sine wave is depicted in Figure 1. The continuity of the signal, theoretically there are an infinite amount of points between $[0, 2\pi]$, makes it impossible to represent within a digital system. The signal needs to be sampled.

A sampled sine wave, useful for signal processing can be seen in Figure 2. Conceptually, sampling a signal means assigning each of the infinite amount of points to a finite number of bins in a grid. The sampling rate defines the horizontal granularity of the grid, the bit depth defines the vertical granularity. A sample rate of 44.1kHz and a bit depth of 16bits creates a fine enough grid for music.

⁹For the more visually inclined, these concepts are also explained in *A Digital Media Primer for Geeks* by Monty of the Xiph foundation: <https://www.xiph.org/video/vid1.shtml>

¹⁰See e.g. <http://people.xiph.org/~xiphmont/demo/neil-young.html>

Figure 1: Continuous sine wave

Figure 2: Sampled sine wave

The listing 6 shows how equation 1 translates to source code. The first four lines define the properties of the sampled wave, the frequency, amplitude, sample rate, and duration. For performance reasons $2\pi f$ is calculated before the loop starts, on line 5. Line six initializes the buffer, where the audio information is stored. The for loop (lines 7 - 10) construct is used to calculate the value of every sample.

Listing 1: A sampled sine wave

```

1 double sampleRate = 44100.0;
  double frequency = 440.0;
  double amplitude = 0.8;
  double seconds = 2.0;
  double twoPiF = 2 * Math.PI * frequency;
6 float[] buffer = new float[(int) (seconds * sampleRate)];
  for (int sample = 0; sample < buffer.length; sample++) {
    double time = sample / sampleRate;
    buffer[sample] = (float) amplitude * Math.sin(twoPiF * time);
  }

```

After executing the code in Listing 6 the buffer contains a two seconds long pure tone of 440Hz, sampled at 44.1kHz. 440Hz is chosen because it is used as the general tuning

standard for musical pitch. On line 9, each sample is calculated using the `Math.sin` function and is converted to a `float` following the advice found in the Java Language Basics Tutorial¹¹:

It is recommended to use a float (instead of double) if you need to save memory in large arrays of floating point numbers. This data type should never be used for precise values, such as currency.

Pure sine tones are not commonly found in the wild. Most sounds in the real world have a rich harmonic spectrum. The following example shows a sound with one harmonic at 6 times the base frequency. The mathematical representation can be seen in equation 2. The example could be expanded with more harmonics. If you choose the harmonics carefully, a realistic sustained flute sound could be synthesized, only by adding more harmonics.

$$f(x) = 0.8 \times \sin(2\pi f) + 0.2 \times \sin(2\pi 6f) \quad (2)$$

Figure 3: A continuous and discrete complex wave representing equation 2.

Figure 5 shows continuous and sampled versions of the wave represented by equation 2. Interesting to note is the visual superposition of the harmonic onto the wave with the base frequency. This superposition is the result of the addition in equation 2. Creating a buffer with this information:

¹¹<http://java.sun.com/docs/books/tutorial/java/nutsandbolts/datatypes.html>

Listing 2: A complex wave buffer

```
double sampleRate = 44100.0;
double seconds = 2.0;

double f0 = 440.0;
5 double amplitude0 = 0.8;
double twoPiF0 = 2 * Math.PI * f0;

double f1 = 6 * f0;
double amplitude1 = 0.2;
10 double twoPiF1 = 2 * Math.PI * f1;

float[] buffer = new float[(int) (seconds * sampleRate)];
for (int sample = 0; sample < buffer.length; sample++) {
    double time = sample / sampleRate;
15 double f0Component = amplitude0 * Math.sin(twoPiF0 * time);
    double f1Component = amplitude1 * Math.sin(twoPiF1 * time);
    buffer[sample] = (float) (f0Component + f1Component);
}
```

Line 17 of listing 2 shows how the two frequency components are being summed up, resulting in a buffer with the correct audio information. The next step is to convert the `float` buffer into pulse code modulated (PCM) bytes, which are understood by e.g. a sound card.

2.2. And Then There Was ... Sound

A conversion step is needed before the sound can be heard. The `float` buffer contains numbers in the range $[-1.0, 1.0]$. Those need to be mapped to e.g. 16bit signed little endian PCM. This can be done by multiplying with $[(2^{16} - 1)/2] = 32767$. Every sample is then 16 bits or two bytes, each sample is converted to two bytes. In Java lingo: the byte array needs to be twice the length of the `float` array.

Listing 3: Converting floats to bytes

```
final byte[] byteBuffer = new byte[buffer.length * 2];
2 int bufferIndex = 0;
for (int i = 0; i < byteBuffer.length; i++) {
    final int x = (int) (buffer[bufferIndex++] * 32767.0);
    byteBuffer[i] = (byte) x;
    i++;
7 byteBuffer[i] = (byte) (x >>> 8);
}
```

To make the sound audible it can be written to a WAVE file. A WAVE file consists of a header followed by the sound data. The sound data is nothing more or less than the PCM format we calculated. The WAVE file header¹² format stems from the time that

¹²More information can be found on this webpage:

<http://www-mmsp.ece.mcgill.ca/documents/audioformats/wave/wave.html>

Microsoft and IBM were still best friends, it is defined in a joint specification[5]. Writing headers is a bit boring luckily there are a few utility classes available in the standard Java library in the `javax.sound.sampled` package which make this task effortless:

Listing 4: Writing a WAV-file

```
File out = new File("out.wav");
2 boolean bigEndian = false;
  boolean signed = true;
  int bits = 16;
  int channels = 1;
  AudioFormat format;
7 format = new AudioFormat(sampleRate, bits, channels, signed, bigEndian);
  ByteArrayInputStream bais = new ByteArrayInputStream(byteBuffer);
  AudioInputStream audioInputStream;
  audioInputStream = new AudioInputStream(bais, format,buffer.length);
  AudioSystem.write(audioInputStream, AudioFileFormat.Type.WAVE, out);
12 audioInputStream.close();
```

Once the WAVE file is stored to disc you can listen to it using about any media player. This is a bit of a drag so another option is to send the sound to the speakers directly. To get this working you need a, for the Java subsystem, correctly configured default sound card¹³.

Listing 5: Play a buffer

```
SourceDataLine line;
DataLine.Info info;
3 info = new DataLine.Info(SourceDataLine.class, format);
  line = (SourceDataLine) AudioSystem.getLine(info);
  line.open(format);
  line.start();
  line.write(byteBuffer, 0, byteBuffer.length);
8 line.close();
```

Within TarsosDSP conversion from bytes to samples is done automatically, but it remains important to know what happens behind the scenes e.g. to look for performance bottlenecks. Once the basic conversions are covered, the next step is to perform operations on sound.

¹³By default the Java Runtime provided by Oracle or Sun does not play nice with PulseAudio on Linux. To allviate this problem see the tutorial here: http://tarsos.0110.be/artikels/lees/PulseAudio_Support_for_Sun_Java_6_on_Ubuntu

3. Operations on Sound

Operations on sound are commonly done in blocks. Operations on individual samples are most of the time not efficient nor practical. E.g. if you would want to estimate the frequency of audio you would need at least one complete period of the signal, surely more than one sample.

For most standard operations, like filtering or an echo, a block size of 1024^{14} samples is common. With the default sample rate of $44.1kHz$ this means that each operation is done on a block of audio of $1024/44.1kHz = 23.21ms$. This block size provides a practical trade-off between computational performance, update speed and usability. Depending on the operation, larger block sizes might add a too large delay, smaller ones might not provide enough audio-information to be able to perform the wanted operation.

Chaining operations is also common. An architecture that allows a chain of arbitrary operations on audio blocks of arbitrary size results in a flexible processing pipeline. These concepts are implemented in the TarsosDSP audio library. Figure 4 shows the processing pipeline. Currently, only single channel audio is allowed, which helps to makes the processing chain extremely straightforward¹⁵. A schematic representation can be found in Figure 4. The source of the audio is a file, a microphone, or an empty stream. The `AudioDispatcher` chops incoming audio in blocks of a requested number of samples, with a defined overlap. Subsequently the blocks of audio are scaled to a float in the range $[-1, 1]$, as mentioned in Section 2.1. The blocks are encapsulated in an `AudioEvent` object which contains a pointer to the audio, the start time in seconds, and has some auxiliary methods, e.g. to calculate the energy of the audio block.

Figure 4: A schematic representation of the TarsosDSP processing pipeline. The incoming audio (left) is divided into blocks. Each block is encapsulated in an `Event` object by the `Dispatcher`. The event objects flow through one or more `Processor` blocks, which may or may not alter the audio and can generate output (e.g. pitch estimations). Dotted lines represent optional flows.

The `AudioDispatcher` sends the `AudioEvent` through a series of `AudioProcessor` objects which execute an operation on audio. The core of the algorithms are contained

¹⁴The size of a block is often a power of two, mainly because this eases implementation of several algorithms, either in hardware or software. E.g. the FFT algorithm is easy to implement with blocks the size of a power of two. In TarsosDSP the FFT algorithm allows other block sizes as well.

¹⁵Actually multichannel audio is accepted as well, but it is automatically downmixed to one channel before it is send through the processing pipeline

in these `AudioProcessor` Note that the size of a block of audio can change during the processing flow. This architecture supports three types of operations on sound:

Analysis

During sound analysis a certain feature of audio is extracted. The sound itself is not altered. Examples of analysis operations are estimating pitch, calculating loudness (see section 3.1), and detecting onsets. Some analysis operations need only one block of audio, like estimating pitch. Other operations compare the current block of audio with a few previous blocks, this is done in some onset detection methods. A third kind of audio analysis operations can not operate in real-time, since they need information on previous and future blocks of audio. For example, reliable beat tracking can only be done by post-processing onsets.

Audio Effects

An operation is called an effect when it uses an audio stream as input and alters it in a certain way. Examples of audio effects include flanger, filters, pitch shifting, phaser, echo (see section 3.2), and chorus. Time stretching, altering the speed of audio without affecting its pitch, is a special kind of audio effect since it changes the length of the audio (block), while the others do not.

Synthesis

When audio is generated using only a mathematical construct, or prerecorded samples, an audio synthesis operation takes place. The main difference with an effect is that it is not dependent on audio input. Generating random noise is one of the more simple synthesis operations.

The following examples are excerpts from the library and illustrate how each operation type is implemented within TarsosDSP.

3.1. Audio Analysis - Sound Detection

This section describes how to implement a program that reacts to the presence of sound: when the sound level reaches a certain threshold the algorithm sends a notification. This functionality can e.g. be used to implement a burglar alarm system.

A sound detection algorithm has to calculate the energy of the signal. Audio signal energy is commonly expressed in decibel sound pressure level (dBSPL), a logarithmic unit. Since the human ear has a large dynamic range¹⁶ a logarithmic unit is practical. To calculate the dB SPL level of a buffer b of length n use the following formula:

$$20 \log_{10} \frac{\sqrt{\sum_{i=0}^n b[i]}}{n}$$

¹⁶The ratio of the quietest sound the ear can hear and the loudest the ear can bear is about 10^{12} .

For this applications the size of the buffer does not matter that much. The size should span some time to make the measurement more meaningful but if the buffer is too large the response time of the algorithm suffers, e.g. a buffer of 10240 samples gives a minimal delay of $232ms$ at $44100Hz$. For this application buffers from 512 to 4192 samples make sense (causing a delay from 12 to 95ms).

The flow of the program is straightforward. Each block of audio is analyzed and a decibel value is calculated. If the value reaches a certain threshold sound is present, otherwise silence is assumed. With the TarsosDSP library this can be implemented as follows:

Listing 6: Detecting sound or silence

```
// create a new dispatcher
2 AudioDispatcher dispatcher;
dispatcher= AudioDispatcher.fromDefaultMicrophone(1024, 0);
dispatcher.addAudioProcessor(new AudioProcessor() {
    float threshold = -70;//dB
    @Override
7   public boolean process(AudioEvent audioEvent) {
        float[] buffer = audioEvent.getFloatBuffer();
        double level = soundPressureLevel(buffer);
        if(level > threshold){
            System.out.println("Sound detected.");
12        }
        return true;
    }

    @Override
17   public void processingFinished() {}

    /**
     * Returns the dB SPL for a buffer.
     */
22   private double soundPressureLevel(final float[] buffer) {
        double power = 0.0D;
        for (float element : buffer) {
            power += element * element;
        }
27   double value = Math.pow(power, 0.5)/ buffer.length;;
        return 20.0 * Math.log10(value);
    }
});
```

3.2. Audio Effects - Echo

As an example of a simple audio processing operation an echo effect, a delay, is implemented. The idea of this section is, next to showing how an echo effect works, to explain audio manipulation by processing blocks.

Figure 5: Block diagram representing a delay audio effect. The input is mixed with delayed and scaled output.

3.3. Synthesis - Sawtooth wave

3.4. Pitch Detection

TarsosDSP implements several pitch detection methods. YIN [2], the McLeod Pitch Method[7] and the Dynamic Wavelet pitch estimation algorithm [6]

3.5. Time-Scale Modification in Time Domain

TarsosDSP contains an implementation of the time stretching algorithm described in [13], it can playback audio quicker or slower without affecting changing pitch. Slow playback is e.g. very practical to transcribe the melody of a song.

3.6. Percussion Detection

The onset detector implementation is based on a VAMP plugin example by Chris Cannam at Queen Mary University, London. The method is described in [1].

3.7. Filtering

In the `be.hogent.tarsos.dsp.filters` package several frequency filters can be found. With a high pass filter, audio with frequencies above a certain threshold are kept. A low pass filter does the reverse, audio with frequencies below a threshold is kept. Together they can create a band pass filter which can e.g. be constructed to focus on the melodic range of a song and ignore the rest.

This document is a work in progress, for more information see the source code on <https://github.com/JorenSix/TarsosDSP> ;).

A. TarsosDSP Readme file

TarsosDSP is a Java library for audio processing. Its aim is to provide an easy-to-use interface to practical music processing algorithms implemented, as simply as possible, in pure Java and without any other external dependencies. TarsosDSP features an implementation of a percussion onset detector and a number of pitch detection algorithms: YIN, the Mcleod Pitch method and a Dynamic Wavelet Algorithm Pitch Tracking algorithm. Also included is a Goertzel DTMF decoding algorithm, a time stretch algorithm (WSOLA), resampling, filters, simple synthesis, some audio effects, and a pitch shifting algorithm.

To show the capabilities of the library, TarsosDSP example applications¹⁷ are available. Head over to the TarsosDSP release directory¹⁸ for freshly baked binaries and code smell free (that is the goal anyway), oven-fresh sources.

A.1. Quickly Getting Started with TarsosDSP

Head over to the TarsosDSP release repository¹⁹ and download the latest TarsosDSP library²⁰. To get up to speed quickly, check the TarsosDSP Example applications²¹ for inspiration and consult the API documentation²².

TarsosDSP is also published in the main Maven repository. This makes it easier to use TarsosDSP in Maven projects.

A.2. TarsosDSP Example Applications

TarsosDSP contains some ready made example applications. Most have a Java Swing user interface. They show which functionality is present in the library and how to use it.

- SoundDetector²³ show how you loudness calculations can be done. When input sound is over a defined limit an event is fired.
- PitchDetector²⁴ this demo application shows real-time pitch detection. When pitch is detected the hertz value is printed together with a probability.

- PercussionDetector²⁵ show the percussion (onset) detection. Clapping your hands causes an event. This demo application also shows the influence of the two parameters on the algorithm.
- UtterAsterisk²⁶ a game with the goal to sing as close to a melody a possible. Technically it shows real-time pitch detection with YIN or MPM.
- Spectrogram in Java²⁷ shows a spectrogram and detected pitch, either live or from an audio file. It is interesting to see which frequencies are picked as fundamentals.
- a²⁸n implementation of the Goertzel Algorithm. A fancy user interface shows what goes on under the hood.
- Audio Time Stretching Implementation in Pure Java Using WSOLA²⁹ an implementation of a time stretching algorithm. WSOLA makes it possible to change the play back speed of audio without changing the pitch. The play back speed can be changed at any moment, even when there is audio playing.
- Audio Feature Extraction³⁰ a command line application to do simple feature extraction.
- Audio Synthesis³¹ a command line application to do simple audio synthesis.
- Pitch Shifting³² an example application that does pitch shifting, either in real-time on a microphone input, or on recorded audio. Also included is a command line application to do pitch shifting.

A.3. Developing TarsosDSP

If you want to build from source, or want to improve TarsosDSP follow the instructions below. Contributions to TarsosDSP are more than welcome, if you have a an algorithm to add or find a bug, do not hesitate to send me a message.

TarsosDSP is in the transition between Apache Maven³³ and Apache Ant³⁴ and currently supports both. The instructions below detail how you can build from source. Which build system you use is upto you. I find Ant a bit simpler. When everything runs correctly you should be able to run all example applications and have the latest version of the TarsosDSP library for inclusion in your projects. Also the Javadoc documentation for the API should be available.

A.3.1. TarsosDSP with Ant

To you need Apache Ant³⁵ and git³⁶ installed on your system. The following commands fetch the source and build the library and example jars:

```
git clone https://JorenSix@github.com/JorenSix/TarsosDSP.git
cd TarsosDSP
#link the source files at the expected locations
test -f src || ln -s TarsosDSP/src/main/java/ src
test -f examples || ln -s TarsosDSPExamples/src/main/java/ examples
test -f tests || ln -s TarsosDSP/src/test/java tests
cd build
ant tarsos_dsp_library #Builds the core TarsosDSP library
ant build_examples #Builds all the TarsosDSP examples
ant javadoc #Creates the documentation in TarsosDSP/doc
```

A.3.2. TarsosDSP with Maven

To build from source, you need Apache Maven³⁷ and git³⁸ installed on your system. The following commands fetch the source and build the library and example jars:

```
git clone https://JorenSix@github.com/JorenSix/TarsosDSP.git
cd TarsosDSP/TarsosDSP
mvn install #Builds the core TarsosDSP library
mvn javadoc:javadoc #Builds the javadoc for TarsosDSP library
cd ../TarsosDSPExamples
mvn install #Builds all the TarsosDSP examples
```

A.4. Source Code Organization & Developing

The library is separated to 2 projects: TarsosDSP (main core) and TarsosDSPExamples (examples). They have different POM's and are built independently.

³³<http://maven.apache.org/>

³⁴<http://ant.apache.org/>

³⁵<http://ant.apache.org/>

³⁶<http://git-scm.com/>

³⁷<http://maven.apache.org/>

³⁸<http://git-scm.com/>

- TarsosDSP/src contains the source files of the core DSP libraries.
- TarsosDSP/test contains unit tests for some of the DSP functionality.
- TarsosDSP/target/site/apidocs contains help documentation for DSP library
- TarsosDSP/target contains MAVEN build files.
- TarsosDSPExamples/src/main contains a couple of example applications with a Java Swing user interface.
- TarsosDSPExamples/target contains builded versions example applications.
- build contains ANT build files. Either to build Java documentation or runnable JAR-files for the example applications.

To make development with eclipse easy, symlink the following and make them source files in your TarsosDSP eclipse project.

```
test -f src || ln -s TarsosDSP/src/main/java/ src
test -f examples || ln -s TarsosDSPExamples/src/main/java/ examples
test -f tests || ln -s TarsosDSP/src/test/java tests
```

A.5. Credits

Tarsos³⁹ and TarsosDSP⁴⁰ are developed at University College Ghent, Faculty of Music <http://cons.hogent.be>⁴¹

The onset detector implementation is based on a VAMP plugin example⁴² by *Chris Cannam* at Queen Mary University, London. The method is described in Drum Source Separation using Percussive Feature Detection and Spectral Modulation⁴³ by Dan Barry, Derry Fitzgerald, Eugene Coyle and Bob Lawlor, ISSC 2005.

For the implementation of the YIN pitch tracking algorithm. Both the the YIN paper⁴⁴ and the aubio implementation⁴⁵ were used as a reference. *Matthias Mauch* (of Queen Mary University, London) kindly provided the FastYin implementation which uses an FFT to calculate the difference function, it makes the algorithm up to 3 times faster.

The Average Magnitude Difference (AMDF) pitch estimation algorithm is implemented by *Eder Souza* and adapted for TarsosDSP by myself.

⁴⁴http://recherche.ircam.fr/equipes/pcm/cheveign/ps/2002_JASA_YIN_proof.pdf

⁴⁵<http://aubio.org>

For the MPM pitch tracking algorithm, the paper titled A Smarter Way To Find Pitch⁴⁶ by *Philip McLeod* and *Geoff Wyvill* was used.

The Dynamic Wavelet pitch estimation algorithm is described in Real-Time Time-Domain Pitch Tracking Using Wavelets⁴⁷ by Eric Larson and Ross Maddox. The implementation within TarsosDSP is based on the implementation in the Dynamic Wavelet Algorithm Pitch Tracking library⁴⁸ by *Antoine Schmitt*, which is released under the MIT open source licence.

The audio time stretching algorithm is described in An % Overlap-Add Technique Based on Waveform Similarity (WSOLA) For Hight Quality % Time-Scale Modifications of speech⁴⁹ by Werner Verhelst and Marc Roelands. As a reference implementation the WSOLA implementation by *Olli Parviainen* in the SoundTouch an open-source audio processing library⁵⁰ was used.

The FFT implementation used within TarsosDSP is by *Piotr Wendykier* and is included in his JTransforms library⁵¹. JTransforms is the first, open source, multithreaded FFT library written in pure Java.

The sample rate conversion feature is implemented by *Laszlo systems* in the libre-sample4j⁵² library. libre-sample4j is a Java port of Dominic Mazzonis libesample 0.1.3, which is in turn based on Julius Smiths Resample 1.7 library⁵³.

Various FFT window functions are done by Damien Di Fede and Corban Brook for the GPL'd Minim⁵⁴ project.

Beat induction based on onsets and saliences is done using code from Simon Dixons BeatRoot system⁵⁵ the algorithm is documented in the 2001 JNMR paper *Automatic Extraction of Tempo and Beat From Expressive Performances*⁵⁶ and in the 2007 JNMR article *Evaluation of the Audio Beat Tracking System BeatRoot*⁵⁷

A complex domain onset detection function is implemented using Aubio as an inspiration. Aubio, by *Paul Brossiers* contains very clean object oriented c-code, the cleanest c-code I have ever seen. The algorithm is described in *Complex Domain Onset Detection for Musical Signals*⁵⁸ by Christopher Duxbury, Mike E. Davies, and Mark B. Sandler, in Proceedings of the Digital Audio Effects Conference, DAFx-03, pages 90-93, London,

A.6. Changelog

Version 1.0

2012-04-24

First release which includes several pitch trackers and a time stretching algorithm, amongst other things. Downloads and javadoc API can be found at the TarsosDSP release directory⁵⁹

Version 1.1

2012-06-4

Changed how the audio dispatcher stops. Added StopAudioProcessor.
Added FastYin implementation by Matthias Mauch
Added AMDF pitch estimator by Eder Souza

Version 1.2

2012-08-21

Modified the interface of PitchDetector to return a more elaborate result structure with pitch, probability and a boolean is pitched.
Added an implementation of an envelope follower or envelope detector.

Version 1.3

2012-09-19

TarsosDSP can do audio synthesis now. The first simple unit generators are included in the library.
It has a new audio feature extraction feature, implemented in the FeatureExtractor example.
Added ASCII-art to the source code (this is the main TarsosDSP 1.3 feature).

Version 1.4

2012-10-31

Included a resample feature, implemented by libresample4j. Together with the WSOLA implementation, it can be used for pitch shifting (similar to Phase Vocoding). A pitch shifting example (both with a CLI and a UI) is added in the 1.4 version of the TarsosDSP library as well.

Version 1.5

2013-04-30

Converted TarsosDSP to maven. This is known as the Malaryta-release. The Malaryta release is provided to you by RikkiMongoose⁶⁰ (idea, documents, git things) and Ultar⁶¹

⁵⁹<http://tarsos.0110.be/releases/TarsosDSP/>

⁶⁰<http://github.com/rikkimongoose>

⁶¹<http://github.com/ultar>

(converting to maven, refactoring). Malaryta is the capital of Malaryta Raion, Brest Region in the Republic of Belarus. Both of developers spent their childhood in Brest, and think that title Malaryta is as strange as Ubuntu or Whistler. The 1.5 release also includes various FFT window functions from the cool Minim project⁶² by Damien Di Fede.

Version 1.6

2013-06-12

This release features practical onset and beat detection algorithms. A complex domain onset detection and a spectral flux onset detection algorithm are added. This release also includes a way to guess a beat from onsets. Parts of the Beatroot system, by Simon Dixon, are included to this end.

⁶²<http://code.compartmental.net/tools/minim/>
